# FEASABILITY OF USING SEA TURTLE STRANDINGS DATA

# AS A MANAGEMENT/ENFORCEMENT TOOL

## INTRODUCTION

This analysis of the Sea Turtle Stranding and Salvage Network (STSSN) data base was conducted to evaluate the feasibility of using strandings as a real-time management tool for protection of sea turtles  The most recent NMFS Biological Opinion on shrimp trawling in the southeastern United States requires that management actions be taken in response to unusual stranding events. Unusual stranding events are defined as situations where 75% of twice the weekly stranding averages (based on running averages of five) in a given statistical zone have been exceeded for two or more weeks.

The STSSN data base contains records of strandings from 1980 through 1994. Over this time period, major differences have existed in the amount of effort expended in documenting strandings and in the locations where this information was collected. Lack of standardized sampling in the early 1980's and lack of uniformity in survey procedures has resulted in gaps in stranding reports for certain areas and times. The most obvious deficiencies exist in the Gulf of Mexico prior to 1986. To determine if strandings have changed significantly, mean strandings plus or minus two standard errors for all species combined, Kemp's ridleys and for loggerheads using the combination of years 1980-1985 and 1986-1994 were computed and are presented in Table 1.

For all species combined, significant increases in strandings were observed in the Gulf of Mexico but not in the Atlantic. For Kemp's ridleys, significant increases in strandings occurred in both the Gulf of Mexico and the Atlantic. For loggerheads, significant increases were not observed in the Atlantic but were evident in the Gulf. We attribute the Gulf of Mexico increases in loggerhead strandings and part of the increase in Kemp's ridley strandings to increased stranding

network effort after 1985. The remainder of the ridley increase which occurred in both the Atlantic and Gulf is attributed to increases in abundance. Since one of the objectives of this analysis is to establish a baseline for comparison with future strandings, inclusion of Gulf of Mexico data from the early 1980's does not appear to be appropriate.

In determining which years should be used in calculation of a baseline for mean strandings, there are complicating factors other than changes in stranding network effort. The largest area of uncertainty is the effects of on-again/off-again federal protective measures requiring turtle excluder devices (TEDs) in shrimp trawls. TEDs were first required in 1987, but due to a series of legal challenges and Congressional actions, were not fully implemented in offshore waters until 1990 and in inshore waters until 1994. Throughout the TED phase-in process, strandings have fluctuated greatly but have apparently not diminished despite the fact that TEDs are now required at all times in all places.

The years 1986 and 1994 had higher strandings than any other years, and it has been suggested that these years should be excluded from calculations to avoid biasing means upward. Others have argued that these years should be included in the data base because stranding events may be cyclic in nature and these years may not be aberrant. To address these concerns, our computations were conducted both using 1994 data and excluding these data.

Another area of consideration was species composition of strandings. The most common turtle in the strandings is the threatened loggerhead, Caretta caretta. The highly endangered Kemp's ridley, Lepidochelys kempi, is second most abundant in the stranding data base. From a management standpoint, it may be more important to identify unusual events adversely affecting the Kemp's ridley than events impacting only loggerhead turtles. Therefore, we conducted analyses using all turtle strandings and separate analyses using only Kemp's ridley strandings employing the following data sets:

1. Years 1987 to 1993 combined
2. Years 1987 to 1994 combined
3. Years 1990 to 1993 combined
4. Years 1990 to 1994 combined

Based on the above analyses, a decision was made to use data from all strandings and the years 1990 through 1993 in establishing a baseline stranding level for comparison with future strandings. This selection was influenced by management's determination that 1994 and 1986 exhibited unacceptably high strandings, and that strandings of this magnitude warranted action. The years 1987 through 1989 were excluded because of uncertainties regarding utilization of TEDs over that time period, and reluctance to include data where TEDs were partially implemented. After 1990, TEDs were required in all offshore

waters at all times, and these regulations are currently in effect.

## ANALYTICAL APPROACH

Several analytical approaches were evaluated to determine which provided the most useful indices of strandings. The data base was somewhat difficult to work with because only documented strandings were reported. Zeros are not included for areas and times when effort was expended and no turtles were found. The breakdown of the data base to weekly strandings by statistical zone required construction of a matrix containing cells with zero values in areas and weeks where no strandings were reported. Once the matrix was constructed, the question of normal versus non-normal distribution of the data was addressed. Initially, weekly strandings in each zone/week/year combination were examined using Wilk's test (SAS Univariate procedure) to determine whether the assumption of normal distribution or log-normal distribution was most appropriate. The results of this analysis were inconclusive. As anticipated, in some statistical zone/week/year cells, log-normal offered a better fit while in other cells, normal distribution offered a better fit. Overall, the normal distribution appeared to offer the better fit for the majority of statistical zones/weeks/years. For comparative purposes only, the data were analyzed assuming normal distribution and again using a distribution free approach.

Based on the above preliminary analyses, we determined that a distribution free percentile approach would be most appropriate for analysis of standings data. To increase the number of data points used in computing percentiles and to avoid large fluctuations in weekly values, moving averages of five weeks were employed. This resulted in 20 data points per week (four years * five weeks) to be used in computing 90 and 95th percentiles on a weekly basis for all statistical zones.

The breakdown of the data to statistical zones by week resulted in low mean values for many areas and times, which under the current management regime would trigger actions based on a few strandings. To avoid this problem, we employed a second approach which treated large areas (for example, the northern Gulf of Mexico - statistical zones 10-21) as single units. The distribution of the fleet within each unit at a given time would be highly variable, but assuming that total weekly effort was relatively constant between years, total weekly mortalities for the larger areas should also remain constant. The 90 and 95th percentiles were computed as described above for zones 10-21 combined, 1-9 combined, 24-29 combined and 30-35 combined.

In addition to the two approaches described above, a third set of values was computed based upon mean cumulative strandings

through a specific week. This approach provides information on whether a particular stranding event is of such a magnitude that cumulative strandings through that week significantly exceed historical cumulative strandings through that week. In computation of cumulative values, one-sided confidence intervals based upon the assumption of normal distribution were constructed. For this analysis, moving averages of five were not used, thus limiting the sample sizes to four. The distribution free approach was judged to be inappropriate in this case due to the lower sample sizes.

Using the three approaches described above, we computed weekly means and one-sided confidence intervals by statistical zone, by large areas combining statistical zones, and cumulatively for large areas. Results are presented in Apendices 1, 2 and 3.

## MANAGEMENT TRIGGERS

The objective of the above analysis was to provide management with summary statistics of past sea turtle strandings in the Gulf of Mexico and southern North Atlantic. Three indices of strandings were produced to aid management in determining whether a current stranding event is unusual with respect to past years. The mean values and confidence limits presented should not be interpreted as limits beyond which the recovery of species might be compromised. These values are simply reflective of past strandings; no evaluation of the biological consequences of strandings was attempted nor is any such evaluation implied.

The determination of what level of strandings should be established to trigger management actions is not a statistical question. Any value for a particular unit area can be set based upon perceptions of what constitutes an unacceptably high number of strandings. As the most appropriate management guidelines, we recommend using the combination of approaches described above which include the parametric one sided cumulative trigger limits and the nonparametric 90 percentile limit.

## VALIDATION

Using the values computed, we tested historical data to determine when, and if, observed strandings exceeded our calculated values using the three approaches. For example, 1986 was a year of unusually high strandings, and we expected our calculated values to be exceeded in certain statistical zones at certain times during that year. The year 1994 was also unusual and we would expect our values again to be exceeded at several

times during the year. Many of the intervening years were relatively normal in terms of strandings and we would not expect triggers to be activated during those years.

This validation process flagged 1986 and 1994 where stranding rates were extremely high and where management actions were probably warranted. During the intervening years, occasional events exceeded our calculated values but rarely for all three computations. In all cases where management actions were taken over the time period, our calculated values were exceeded.

Based on the above validation tests, it is our recommendation that the three separate computations be used in conjunction for management decisions. As weekly stranding reports are entered in the computer, analyses could be conducted to determine whether weekly trigger limits for any statistical zone were exceeded. A second analysis would determine whether computed values for combinations of zones were exceeded during that week. A third analysis would determine whether cumulative values for the same combination of zones up to that week had been exceeded. If all three values were exceeded, area closures or other management actions would be warranted. If one or two of these values were exceeded, additional enforcement could be initiated to determine the probable cause of higher than expected mortalities. A programs used in our analysis could be used on a weekly basis, and reports identifying potential problem areas could be provided to SERO. The obvious limitation of this approach is that data from all statistical zones for a given week must be collected and entered before these analyses can be conducted.

## DISCUSSION

The above statistical approaches to using stranding information as a real-time management tool are logical, and may be the best means of using stranding data to initiate management actions. Use of three independent indices allows management to identify local events, and then to evaluate the magnitude of impacts of local events as related to larger areas on a weekly and cumulative basis. The greatest weaknesses in the approach are uncertainties about the strandings themselves, lack of consistent effort and reporting of strandings in specific areas, and serious questions about how strandings should be interpreted. These weakness bring into question the validity of any statistical analysis conducted on a data set of this nature.

Perhaps the greatest problem with use of strandings data as a real-time management tool for turtle protection is that we do not know what portion of the turtles that die in a given area will ultimately strand. There is a growing body of evidence suggesting that strandings in fact, reflect nearshore mortalities when tides, winds, currents, etc. are predominately onshore. If

environmental conditions favor offshore movement of turtle carcasses, there may be considerable mortality with no strandings. Also, as the shrimp fleet moves further from shore chances of strandings diminish, but mortality rates may not diminish unless turtle densities are lower.

Strandings are directly related to the presence of beaches and accessibility of coastline. Chesapeake Bay, Core Sound, Florida Bay, the area from Clearwater, FL to Apalachicola, most of the Louisiana coast, etc. are areas where sea turtles are unlikely to be found even if mortalities occur. Many of these areas do not have accessible beaches, and coastlines are composed of extensive salt marshes. Given logistic constraints of sampling coastlines from small boats, an adequate index of turtle mortalities cannot be obtained for such areas. Furthermore, direct comparisons between areas (statistical zones) are seldom possible due to differences in coastlines and accessibility.

Another problem with linking management actions to strandings is that they reflect mortalities that could be far removed from the site of actual stranding in both time and space. It is difficult to determine where stranded turtles were killed (currents, winds, tides, etc. passively transport carcasses), or when the turtle died (state of decomposition is a subjective observation). For this reason, a stranding event in one area may reflect heavy fishing activity in a different area one or two weeks earlier. Any management actions based on a stranding event must therefore be broad in scope. It is also important to note that the operation of the shrimp fleet is such that vessels congregate and disperse as concentrations of shrimp are located and exploited. The vessels involved in a given stranding event may have already dispersed by the time turtles begin to wash ashore and actions can be taken.

Using past strandings in statistical zones as the only trigger for management actions is problematic. Statistical zones are based on arbitrary boundaries (latitudinal and longitudinal) of unequal shoreline distance with unequal levels of observational effort. The operation of the fleet is such that effort may be concentrated in different statistical zones throughout the year and between years. There is also a problem when strandings are located near statistical zone boundaries - should one or both statistical zone be closed? High strandings in any given statistical zone may reflect the location of the fleet, but may not be indicative of unusual problems. The opening of Texas waters if an example of concentrating most northern Gulf effort in one place at one time.

High stranding rates followed by lower stranding rates in a given area do not necessarily imply that management actions have been successful. When fishing seasons open, high levels of effort on large turtle populations can result in unusually high strandings. As turtle populations are reduced, strandings will decrease regardless of whether management actions are taken or

not. Also, the fleet may simply leave an area as shrimp catches diminish.

Another problem with use of historical stranding totals to trigger management actions is that provisions have not been made for dealing with increasing populations. If TEDs are even half as effective as we believe, Kemp's ridley populations could have increased significantly over the past few years. Increased populations mean increased CPUE and increased mortality if nothing changes in operation of the shrimp fleet or TED utilization. If population increases become exponential (this is not out of the realm of possibilities for Kemp's ridleys) closures could be mandated for the wrong reasons. Furthermore, if populations were decreasing (a situation where management actions would be imperative) historical stranding means and triggers based on these means would never activate management actions because number of dead turtles would diminish as populations decreased. Under a scenario of decreasing populations, management based on current emergency plans would be totally ineffective for protection of endangered and threatened turtles.

These are a few of the obvious pitfalls in using stranding information to trigger or evaluate management actions. Some other factors that could influence stranding rates include: type of TED used (soft of hard) and its configuration (upward or downward shooting), level of compliance with TED regulations, size and location (offshore or inshore) of the fleet, state and federal closures which redistribute effort, average length of tows, other activities in the area (dredging, explosive platform removal, gill netting, purse seining, vessel traffic, etc.), temperature (air and water as related to turtle metabolism), species of turtles encountered, size of turtles encountered, environmental conditions, target species of shrimp and type of nets used (flat or high opening wing nets), try net capture and mortality, etc., etc.

Because of the problems associated with interpretation of strandings and because stranding effort and reporting has been inconsistent between statistical zones, there are major problems in using this information to trigger real-time management actions. As indicators of problem areas that may require management attention, strandings are fine. It is when a specific number of strandings in an area are linked to specific management actions, such as closures, that serious questions must be raised. In our view, each so-called stranding event is different and may require different management approaches to protecting sea turtles. Management should use the proposed approaches as tools for evaluating each event and not be compelled to initiate specific management actions based on exceeding some or all triggers.

We conclude that there are major shortcomings in use of strandings as a real-time management tool, but the only viable

alternative may be placement of observers aboard shrimp trawlers. Observer programs are prohibitively costly, and the amount of effort required to obtain reliable estimates of turtle mortalities for the fleet is unrealistically high. Because adequate funding for an observer program is unlikely to become available, management based on strandings would appear to be the best that can be done.

**APPENDIX I.** Weekly computations of 90 and 95th percentiles by statistical zone based on data from the years 1990 through 1993. Weekno=week, N=number of years, Min=minimum strandings, Max=maximum strandings, Sum=total standings used in computations, mean=mean, std=standard deviation, stderr=standard error of the mean, NMA=number of data points used in computation based on a moving average of five, MEANMA=mean (moving average of five), SUMMA=total number of strandings (moving average of five), STDMA=standard deviation (moving average of five), MAXMA=maximum strandings (moving average of five), MINMA=minimum strandings (moving average of five), P90MA=90th percentile (moving average of five), P95MA=95th percentile (moving average of five).

**APPENDIX III(a).** Weekly computations of cumulative 90 and 95th one-sided confidence limits for statistical zones 1-9 combined using the years 1990 through 1993. Weeks and years (1986 through 1994) in which the calculated values for this combination of zones were met or exceeded are calculated.

**APPENDIX III(b).** Weekly computations of cumulative 90 and 95th one-sided confidence limits for statistical zones 10-21 combined using the years 1990 through 1993. Weeks and years (1986 through 1994) in which the calculated values for this combination of zones were met or exceeded are calculated.

**APPENDIX III(c).** Weekly computations of cumulative 90 and 95th one-sided confidence limits for statistical zones 24-29 combined using the years 1990 through 1993. Weeks and years (1986 through 1994) in which the calculated values for this combination of zones were met or exceeded are calculated.

**APPENDIX III(d).** Weekly computations of cumulative 90 and 95th one-sided confidence limits for statistical zones 30-35 combined using the years 1990 through 1993. Weeks and years (1986 through 1994) in which the calculated values for this combination of zones were met or exceeded are calculated.
